

## PACOTE UNCERTAINTIES

O pacote uncertainties é um programa gratuito de plataforma cruzada que lida de forma transparente com cálculos contendo incertezas (como  $3,14 \pm 0,01$ ). Também pode produzir os derivados de qualquer expressão. Sintaxe:

```
var = unfloat(valor, incerteza)
```

Para instalar o pacote, execute a célula abaixo:

```
In [65]: !pip3 install --upgrade upandas
```

```

## INTERPOLAÇÃO

Os resultados de medições experimentais ou simulações numéricas fornecem, em geral, um conjunto de valores de uma função em pontos discretos de uma variável independente. Esses valores podem ser apresentados na forma de uma tabela para valores discretos de  $x$ . O processo de calcular a função para valores intermédios aos valores conhecidos de  $f(x)$  é chamado interpolação ([MIRANDA, 2018](#)).

([https://fenix.ciencias.ulisboa.pt/downloadFile/2251937252639182/LabNum\\_2018\\_v4.pdf](https://fenix.ciencias.ulisboa.pt/downloadFile/2251937252639182/LabNum_2018_v4.pdf)). Tipos de interpolação:

- Interpolação linear (padrão da função `interp1d`)
- Interpolação polinomial
- Interpolação trigonométrica
- Spline

Gráfico interpolação linear:

Sintaxe:

```
# carregar a função interp1d
from scipy.interpolate import interp1d

# calcular a função interpolação
nome_função = interp1d(dados_x, dados_y, kind='tipo_interp')
```

'linear', 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'previous', 'next', where 'zero', 'slinear', 'quadratic' and 'cubic' refer to a spline interpolation of zeroth, first, second or third order; 'previous' and 'next' simply return the previous or next value of the point

## AJUSTE DE CURVAS

Ajuste de Curvas é um método que consiste em encontrar uma curva que se ajuste a uma série de pontos e que possivelmente cumpra uma série de parâmetros adicionais. Ajuste de curvas pode envolver tanto interpolação, onde é necessário um ajuste exato aos dados, quanto suavização, na qual é construída uma função "suave" que se aproximadamente se ajusta aos dados. Outro assunto relacionado é análise de regressão, a qual se foca mais em questões da inferência estatística ([Wikipedia, 2019](https://pt.wikipedia.org/wiki/Ajuste_de_curvas)) ([https://pt.wikipedia.org/wiki/Ajuste\\_de\\_curvas](https://pt.wikipedia.org/wiki/Ajuste_de_curvas)).

Algoritmo:

```
# Definir as constantes
var('k_1', 'k_2', k_3, ..., k_n)

# definir um modelo matemático
modelo(x) = expressão_matemática

# calcular as constantes do modelo
constantes_modelo = find_fit(dados_pontos, modelo, [k_1_i, k_2_i, ..., k_n_i
], solution_dict = True)

# substituir as constantes no modelo
modelo(x) = modelo.subs(constantes)
```

## Modelo polinomial

## Modelo não polinomial

## Movimento harmônico simples

O movimento harmônico simples é o movimento que ocorre em função de uma força restauradora que desloca um determinado corpo de sua posição de equilíbrio e proporcional ao deslocamento. O exemplo mais simples de oscilador harmônico é o sistema massa mola. O gráfico mostra o deslocamento  $x$  em função do tempo  $t$  que obedece à lei de Hook,  $Fx = -kx$ , no qual  $x$  varia senoidalmente com o tempo e pode ser descrito pela função  $x(t) = A\cos(\omega t + \varphi)$ . Sendo  $A$  (amplitude),  $\omega$  (frequência angular) e  $\varphi$  (fase) constantes.

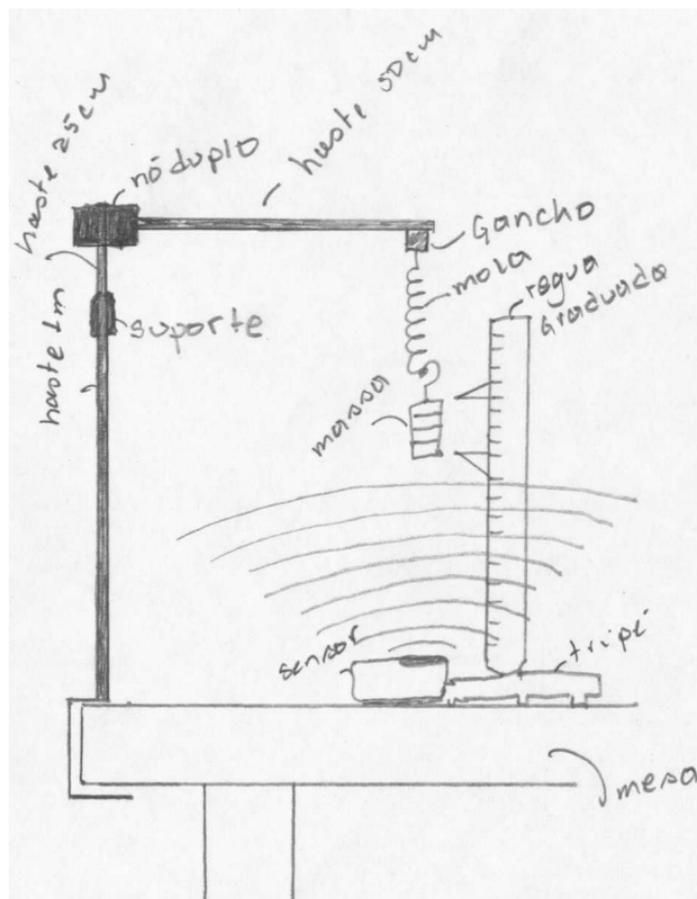

O número de oscilações efetuadas no intervalo unitário de tempo, isto é  $1/T$ , é a *freqüência*  $f$ :

---

$$f = \frac{1}{T} = \frac{\omega}{2\pi} \quad 11.3$$

---

De acordo com o montagem experimental abaixo, foram coletados dados de função posição  $x$  na vertical (cm) em função do tempo (s) e salvos em um arquivo CSV. A partir dos dados, determine a função do movimento harmônico simples.
